

# Yellow Vests, Endogenous Beliefs, and Carbon Tax Aversion

**Thomas Douenne & Adrien Fabre**

*Paris School of Economics, Université Paris 1*

September 2019

Figure: Yellow Vests protesting against taxes

Carbon taxation often considered as the most effective policy to reduce emissions (e.g. Goulder & Parry, 2008). However, cost-effectiveness not the only concern:

- Acceptability problem (Carattini et al, 2018): impact on purchasing power, distributive effects, etc.
- Hence, large literature on revenue recycling, and the popular Tax & Dividend (e.g. West & Williams 2004, Bento et al 2009, Williams et al 2015) including in France (Douenne, 2018).
- Tax & Dividend proposal supported by 3,354 economists in The Wall Street Journal (2019), "To maximize the fairness and political viability of a rising carbon tax".

Carbon taxation often considered as the most effective policy to reduce emissions (e.g. Goulder & Parry, 2008). However, cost-effectiveness not the only concern:

- Acceptability problem (Carattini et al, 2018): impact on purchasing power, distributive effects, etc.
- Hence, large literature on revenue recycling, and the popular Tax & Dividend (e.g. West & Williams 2004, Bento et al 2009, Williams et al 2015) including in France (Douenne, 2018).
- Tax & Dividend proposal supported by 3,354 economists in The Wall Street Journal (2019), "To maximize the fairness and political viability of a rising carbon tax".

→ *With a design that ensures that the tax has desirable properties, we should be able to generate support for carbon taxes.*

**But is it really sufficient?**

# Objective of the paper

In this paper, we run a survey to disentangle *beliefs* from *preferences* over the carbon tax (CT). We:

- investigate whether beliefs about CT properties are consistent with objective ones;
- quantify biases, in particular regarding the costs of CT;
- show persistence of beliefs over CT;
- estimate the role of preferences, i.e. causal effects of holding beliefs on acceptance.

All along, focus on three motives stressed by the literature:

- ① self-interest;
- ② environmental effectiveness;
- ③ progressivity.

# Main results

- ① French people would largely reject a carbon tax policy with uniform lump-sum transfer (Tax & Dividend).
- ② Their perceptions about the properties of the scheme are biased towards over-pessimism.
- ③ Providing information can hardly help correct these misperceptions. Beliefs are persistent, and revisions biased towards information against the tax.
- ④ Nonetheless: if one could convince them, the scheme would reach large majority support.

This paper contributes to two strands of the literature:

- **On the political economy of climate policies.**

*See Carattini et al (2018) for a recent review.*

This paper is the first to:

- ▶ quantify biases regarding the costs of carbon taxation;
- ▶ provide robust evidence for causal effect of several motives on acceptance;
- ▶ show how motivated reasoning could reinforce rejection of climate policies.

- **On endogenous beliefs and how they relate to policies:**

- ▶ show asymmetric updating of beliefs w.r.t. policies depending on information being positive or not. Echoes recent studies that focused on non-policy related news (e.g. *Eil & Rao, 2011; Möbius et al, 2011; Sharot et al, 2011*);
- ▶ provide robust evidence that beliefs shape attitudes, and attitudes shape beliefs (see *Bénabou & Tirole, 2016*), even more so for more educated people;
- ▶ brings empirical evidence supporting theories previously developed (e.g. *Kahan, 2013; Kraft et al, 2015; Little, 2019*).

## 1 Survey and data

## 2 Perceptions

## 3 Are beliefs persistent?

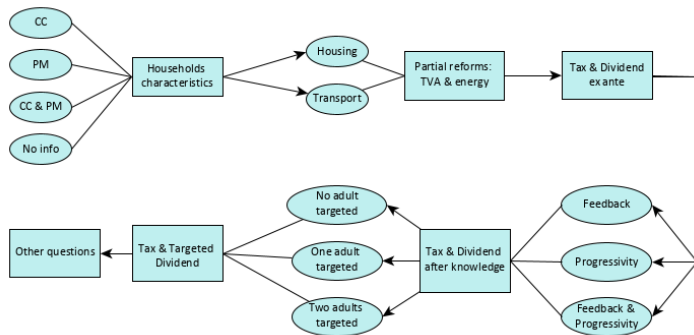

## 4 Motives for acceptance

## 5 Conclusion

# Survey data collection

- 3002 responses collected on-line in February/March 2019
- Representative along: gender, age, education, profession, size of town, region
- Standard procedure to ensure the quality of responses

► See sample characteristics

1 Survey and data

2 Perceptions

3 Are beliefs persistent?

4 Motives for acceptance

5 Conclusion

---

"The government is studying an increase in the carbon tax, whose revenues would be redistributed to *all households*, regardless of their income. This would involve:

- an increase in the price of gasoline by 11 cents per litre and diesel by 13 cents per litre;
- a 13% increase in the price of gas, and a 15% increase in the price of domestic fuel;
- an annual payment of 110€ to each adult, i.e. 220€ per year for a couple.

In terms of purchasing power, would your household win or lose with such a measure?"

---

---

"The government is studying an increase in the carbon tax, whose revenues would be redistributed to *all households*, regardless of their income. This would involve:

- an increase in the price of gasoline by 11 cents per litre and diesel by 13 cents per litre;
- a 13% increase in the price of gas, and a 15% increase in the price of domestic fuel;
- an annual payment of 110€ to each adult, i.e. 220€ per year for a couple.

In terms of purchasing power, would your household win or lose with such a measure?"

---

Then we ask about expected loss (or gain) among 6 (or 5) intervals, and approval:

- 10% 'Yes': approval
- 19% 'PNR (I don't know, I don't want to answer)': acceptance
- 70% 'No': disapproval

## Biased perception of net gain

PDF of **subjective** vs. **objective** net gains from Tax & Dividend (in € per year per consumption unit).

Figure: Net gain. Mean: **-89**/**+24**

- **64%** think they lose; only 14% think they win
- Objectively, **70%** win
- 89% underestimate their gain, 53% by more than 110€.
- Median gap of 116€.

► See prediction's method

# (Not so) heterogeneous bias

**Table:** Determinants of a large bias in subjective gains.

|   | Large bias ( $ \hat{\gamma} - g  > 110$ ) |                     |                      |

⇒ Motivated reasoning (Kunda, 1990): the more opposed to the tax, the more bias? Or opposite direction of causality?

## Beliefs over environmental effectiveness and progressivity

Reform effective to “reduce pollution and fight climate change”?

→ 17% ‘Yes’, 66% ‘No’ and 18% ‘PNR’.

▶ See possible explanations

Reform would benefit poorer households?

→ 19% ‘Yes’, 60% ‘No’, 21% ‘PNR’.

Yet, the tax is progressive!

▶ See distribution per income decile

1 Survey and data

2 Perceptions

3 Are beliefs persistent?

4 Motives for acceptance

5 Conclusion

- Information on the effect of the reform
  - ▶ Feedback: “In five cases over six, a household with your characteristics would [win/lose] through the reform. (The characteristics taken into account are: heating using [energy source] for an accommodation of [surface] m<sup>2</sup>; [distance] km traveled with an average consumption of [fuel economy] L for 100 km.)” (1/2)
  - ▶ Progressivity: “this reform would increase the purchasing power of the poorest households and decrease that of the richest, who consume more energy” (1/3)
  - ▶ or both (to 1/6 of respondents)
- Is the reform beneficial to the poorest? (1/2)
- Would you lose, win or be unaffected by the reform?
- Would you approve this reform?

▶ See prediction's precision

**Table:** Share of respondents with new beliefs aligned with feedback

|  | <i>Aligned with feedback: <math>G^F = \hat{\Gamma}</math></i> |                                 |
|--|---|---------------------------------|
|  | $\hat{\Gamma} > 0$<br>(75.8%)                                 | $\hat{\Gamma} < 0$<br>(24.2%)   |
| Initial belief: winner ( $G > 0$ )<br>(14.0%)      | 78.8%<br>[73.2% ; 83.4%]                                      | <b>81.5%</b><br>[65.0% ; 91.3%] |
| Initial belief: unaffected ( $G = 0$ )<br>(21.7%)  | 21.6%<br>[17.6% ; 26.2%]                                      | 44.9%<br>[33.5% ; 56.8%]        |
| Initial belief: loser ( $G < 0$ )<br>(64.3%)       | <b>12.2%</b><br>[10.3% ; 14.5%]                               | 93.9%<br>[90.9% ; 96.0%]        |
| Initial belief: affected ( $G \neq 0$ )<br>(78.3%) | 26.1%<br>[23.7% ; 28.7%]                                      | 92.9%<br>[89.8% ; 95.1%]        |
| All<br>(100%)                                      | 25.1%<br>[23.0% ; 27.3%]                                      | 85.7%<br>[82.2% ; 88.7%]        |

NOTE: The 95% confidence intervals for binomial probabilities is given in brackets.

# Conservatism and pessimism

Two main results:

- ① Respondents' beliefs are persistent:
  - ▶ on average, they update far less than they should
- ② Respondent's revisions are asymmetric:
  - ▶ they update far less when told that they should win than when told they should lose

Possible interpretations:

- Respondents think our feedback is biased.
- Respondents give too much value to their (biased) private information.
- Respondents are uncertain and risk (or loss) averse: they don't report the expected outcome but something lower.

→ Impossible to disentangle these mechanisms as they all lead to more pessimism.

# Determinants of correct updating

**Table:** Asymmetric updating of winning category

|   | Correct updating ( <i>U</i> )     |                      |                                   |

\*p<0.1; \*\*p<0.05; \*\*\*p<0.01

→ Evidence of motivated reasoning: the more opposed to the tax, the less beliefs are revised following information!

## Beliefs over environmental effectiveness and progressivity

Information randomly displayed about climate change / air pollution / scientific consensus over effectiveness:

→ significant effect on beliefs, but small ( $\simeq 5$  p.p., not significant for air pollution). Beliefs are well anchored!

▶ See table

Correlation between belief that tax is regressive and seeing the information that it is progressive: 0.006% ! How come?

→ evidence of psychological reactance from biased people!

▶ See table

- 1 Survey and data
- 2 Perceptions
- 3 Are beliefs persistent?
- 4 Motives for acceptance
- 5 Conclusion

## Self-interest - Main identification strategy

We propose the same policy as before, except that transfers are now targeted as follows: [▶ See details](#)

$$T_i = \begin{cases} 0, & \text{if } I_i > c_i \\ 1, & \text{otherwise} \end{cases} \quad (1)$$

where  $c_i$  is the income threshold randomly assigned to respondent  $i$ . We can write a Two-Stage Least Square model as follows:

$$G_i^T = \alpha_0 + \alpha_1 T_{1,i} + \alpha_2 T_{2,i} + \alpha_c c_i + \sum_{j=1}^2 (\alpha_{1,j} I_{1,i}^j + \alpha_{2,j} I_{2,i}^j) + \eta_i \quad (2)$$

$$A_i^T = \beta_0 + \beta_1 \widehat{G}_i^T + \beta_c c_i + \sum_{j=1}^2 (\beta_{1,j} I_{1,i}^j + \beta_{2,j} I_{2,i}^j) + \epsilon_i \quad (3)$$

*Identification assumption:* conditional on income and target, being eligible affects approval solely through beliefs of winning.

To ensure the robustness of our results, we run four other specifications:

- The same 2SLS with relevant control variables
- An OLS regression
- A logit regression
- An alternative 2SLS with RDD on the feedback for the first stage:

$$G_i^F = \alpha_0 + \alpha_1 \widehat{\Gamma}_i + \sum_{j=1}^J \alpha_{1,j} \widehat{\gamma}_i^j + \eta_i \quad (4)$$

$$A_i^F = \beta_0 + \beta_1 \widehat{G}_i^F + \sum_{j=1}^2 \beta_{1,j} \widehat{\gamma}_i^j + \epsilon_i \quad (5)$$

*Identification assumption:* conditional on simulated net gains, being simulated winner affects approval solely through beliefs of winning.

**Table:** Effect of self-interest on acceptance

## Environmental effectiveness - Main identification strategy

Two types of exogenous information (randomly displayed) may affect respondents' beliefs about environmental effectiveness:

- Information on scientific agreement about carbon tax efficiency (E)
- Information on climate change (CC)

These variables are both exogenous and *a priori* relevant → we can write a 2SLS as follows:

$$E_i = \alpha_0 + \alpha_1 Z_{E,i} + \alpha_2 Z_{CC,i} + \alpha_C \mathbf{C}_i + \eta_i \quad (6)$$

$$A_i^I = \beta_0 + \beta_1 \hat{E}_i + \beta_C \mathbf{C}_i + \epsilon_i \quad (7)$$

*Identification assumption:* being displayed information affects approval solely through beliefs over policy's environmental effectiveness.

# Environmental effectiveness - Results

**Table:** Effect of believing in environmental effectiveness on acceptance

|                                       | Tax Acceptance ( $A^I$ )  |                  |                            |                     | Tax Approval ( $A^I$ ) |                    |

► First stage results

## Progressivity - Main identification strategy

Could in theory run a 2SLS with random information on progressivity.

*Problem:* Weak instrument... Our info does not convince

Alternative specifications:

- OLS regression with relevant controls
- Logit regression
- Again, distinguish results with 'Yes' vs not No'

*Identification assumption:* conditional on respondents' beliefs over self-gains, environmental effectiveness, their socio-demographic and energetic characteristics, answer on beliefs over progressivity captures approval solely through beliefs over progressivity.

## Progressivity - Results

**Table:** Effect of beliefs over progressivity on acceptance. Covariates refer either to broad (1-4) or strict (5-6) definitions of the beliefs, where strict dummies do not cover “PNR” or “Unaffected” answers.

|  | Acceptance ( $A^P$ ) on not “No” |                      |                     |                     | Approval ( $A^P$ ) on “Yes” |                     |

NOTE: (Standard errors). For logit, average marginal effects are reported

*Question: do these effects complement or substitute?*

Effects of beliefs on approval (strict definitions):

- Three motives: +97 p.p.
- SI & EE: +69 p.p.
- SI & P: +64 p.p.
- EE & P: +74 p.p.

*Altruistic motives matter!*

⇒ Correcting all beliefs (i.e. accounting for the 30% of objective losers): approval rate would go up to 90%!

- 1 Survey and data
- 2 Perceptions
- 3 Are beliefs persistent?
- 4 Motives for acceptance
- 5 Conclusion

## Key results

- ① French people would largely reject a carbon tax policy with uniform lump-sum transfer
- ② Their perceptions about the properties of the scheme are biased:
  - ▶ they over-estimate the negative impact on their purchasing power;
  - ▶ they do not think it is environmentally effective;
  - ▶ they wrongly perceive it as regressive.
- ③ Providing information can hardly help correct these misperceptions:
  - ▶ people give little weight to these information;
  - ▶ they tend to trust more negative news about the tax than positive ones.
- ④ Nonetheless: if one could convince them, the scheme would reach large majority support.
  - ▶ Self-interest, environmental effectiveness and progressivity are critical motives of acceptance:  $\simeq + 40$  p.p. in likelihood to accept for the two firsts,  $+ 27$  p.p. for the latter.
  - ▶ Motives are complementary: correcting biased beliefs would lead to a 90% approval.
  - ▶ Complementarity particularly strong for altruistic motives ( $+74$  p.p. together).

## Key results

- ④ Nonetheless: if one could convince them, the scheme would reach large majority support.
  - ▶ Self-interest, environmental effectiveness and progressivity are critical motives of acceptance:  $\simeq + 40$  p.p. in likelihood to accept for the two firsts,  $+ 27$  p.p. for the latter.
  - ▶ Motives are complementary: correcting biased beliefs would lead to a 90% approval.
  - ▶ Complementarity particularly strong for altruistic motives ( $+74$  p.p. together).

→ *Working on the design of carbon taxes is not enough to ensure their public support. Improving public trust seems necessary for the future of climate policies!*

Go back

- We estimate net gains of respondents using another Insee survey:
  - ▶ *Enquête Logement 2013* (EL): 27,000 HH, good on housing
  - ▶ increase in housing expenditures =  $\beta_0 + \beta_f \text{ fuel} + \beta_g \text{ gas} + \beta_s \text{ surface}$
  - ▶ increase in transport energy expenditures computed directly from HH characteristics
- We estimate the revenues of the reform with the database of Douenne (2018) that matches two Insee surveys:
  - ▶ *Budget de Famille 2011* (BdF): 10,000 HH, good on housing, not on transport
  - ▶ *Enquête Nationale Transports et Déplacements 2008* (ENTD): 20,000 HH, used for transport
- In 83.4% of cases, we predict correctly the winning category (win/lose) on out-of-sample (BdF) data
- Similar (or higher) error rates with other specifications or methods (e.g. regression tree, matching). Adding variables barely improves prediction.

► Go back

We propose the same policy as before, except that transfers are now targeted to adults below some income threshold:

- Respondents allocated to different thresholds: bottom 20, 30, 40 and 50%
  - ▶ Randomly between two thresholds if respondent's income is within them
  - ▶ When income close to only one threshold (i.e. percentile  $< 20$  or in  $[50; 70]$ ), allocated to that one
  - ▶ When percentile is  $> 70$ , threshold determined by spouse's income
  - ▶ If no spouse or if both have high incomes, threshold allocated randomly
- Would you lose, win or be unaffected by the reform?
- Would you approve this reform?
