

Disentangling Beliefs From Preferences Over the French Carbon Tax *

Thomas Douenne and Adrien Fabre

June 2019

Using a new survey and National households' survey data, we investigate French perception over carbon taxation. We find that French people largely reject a tax and dividend policy where revenues of the tax would be redistributed uniformly. However, their perception about the properties of the tax are biased: people overestimate the negative impact on their purchasing power, wrongly think the scheme is regressive, and do not perceive it as environmentally effective. Our econometric analysis shows that correcting these three bias would suffice to generate majority acceptance. Yet, we find that people's beliefs are persistent and their revisions biased towards pessimism, so that only a few can be convinced.

We also thank seminar participants at the Paris School of Economics and an anonymous referee of the FAERE Working Paper series. We would also like to show our gratitude to Stefanie Stantcheva, Michael I. Norton and the Harvard Business School for allowing us to use their Qualtrics account. We acknowledge financial support from the Cepremap, EUR PGSE (ANR-17-EURE-0001) ANR (ANR16-CE03-0011), and Université Paris 1 Panthéon-Sorbonne economics doctoral school (ED 465).

1 Introduction

The French government had initially committed to an ambitious trajectory for the price of carbon. Initiated in 2014 at 7€/tCO₂, the French carbon tax reached 44.6€/tCO₂ in 2018 and was supposed to continue growing to hit 86.2€/tCO₂ by 2022. Yet, at the end of 2018, the same government that had accelerated the price trajectory decided to abandon it and froze the tax at its current level for an undetermined period. This dramatic shift in French climate policy is the direct consequence of the popular protest of the “Yellow Vests”, which started against the carbon tax. Several factors contributed to increase public’s discontent against the tax. The increasing revenues from the carbon tax were mostly used to fund the budget rather than redistributed to households; the policy was concomitant with other unpopular tax reforms, and with high barrel prices. The challenge for economists and policy makers is now to disentangle the determinants of the disapproval, and understand to what extent the rejection reflects intrinsic preferences or biased perceptions over the properties of carbon pricing.

In order to explain French attitudes towards carbon taxation, we conducted a survey on a representative sample of 3,002 French households. We focus on a “Tax & dividend” carbon tax with uniform lump sum compensation, which allows to specify clearly the distributive effects of the policy, at variance with the policy abandoned by the government. The reform is approved by only 10% of respondents and disapproved by 70% (the rest do not know or do not want to answer). We analyze the perceptions of three well-known determinants of acceptance of the carbon tax: the impact on one’s purchasing power, the progressivity of the scheme, and its environmental effectiveness. We compare subjective beliefs elicited from our new survey to objective impacts on respondents’ purchasing power computed using National households’ survey data. This comparison shows that people largely overestimate the negative impact of carbon taxation on their purchasing power. Similarly, while the scheme proposed in our survey is progressive, a large majority of individuals perceive it as regressive. In addition, a majority of respondents do not believe that such policy would reduce pollution and fight climate change. These results suggest that rejection of carbon taxation does not commonly

result from clashing preferences, such as a disinterest for the ecology or a dislike for price
 30 instruments, but rather from biased beliefs about the properties of the reform. To show this
 point, we investigate the effects on acceptance of “rectifying” the beliefs over each of these
 properties. We identify the effect of correcting one’s belief by instrumenting each belief with
 a random treatment: a piece of information randomly displayed or not, or a compensation
 targeted randomly to create exogenous variations in eligibility. A first result is that displaying
 35 information convince only a few people. For example, among those advantaged by the reform
 who wrongly believe they would lose, only 12% are convinced that they would gain when
 we disclose them our estimation. Worse, respondents revise their beliefs in a biased way,
 giving more weight to new information when it shows they would lose from the reform, i.e.
 when it provides them arguments against the tax. That being said, beliefs in self-interest,
 40 environmental effectiveness and progressivity all have a large effect on acceptance: about
 40 percentage points (p.p.) for the first two and 27 p.p. for the latter, other things equal.
 Besides, we find that those who believe the policy is effective have a median willingness to
 pay in the typical range of the literature, at 100€/year per household, suggesting that French
 preferences for climate are not specific. Finally, in a hypothetical scenario where all biased
 45 beliefs could be corrected, we estimate an approval rate of 90%, confirming that the rejection
 is driven by erroneous perceptions.

A growing literature studies attitudes towards climate policies, as this issue is becoming
 critical in the public debate. For a thorough review of this literature, we refer to [Carattini
 et al. \(2018\)](#), and also signal the less recent [Dresner et al. \(2006a\)](#) and the more synthetic
 50 [Klenert et al. \(2018\)](#). Connected literature includes behavioral and political obstacles to en-
 vironmental policies ([Millner & Ollivier, 2016](#)) and willingness to pay for climate mitigation
 ([Jenkins, 2014](#)). Closely related to our paper, [Stern et al. \(1993\)](#) is an early work proposing
 and testing a model of preferences for environmental quality aimed at disentangling ego-
 istic from altruistic motives on the one hand, and beliefs from values on the other hand.
 55 Among all possible attitudes, they show that belief about consequences on self-interest is the
 only predictor of the willingness to pay Pigouvian taxes. Using a post-electoral survey in

Switzerland, [Thalmann \(2004\)](#) also finds a correlation between carbon tax acceptance and self-interest, proxied by the number of cars owned. In surveys on British and Swedish respondents respectively, [Bristow et al. \(2010\)](#) and [Brannlund & Persson \(2012\)](#) document a higher approval when the reform addresses distributional issues. [Baranzini & Carattini \(2017\)](#) report that a majority of the people they interviewed in Geneva do not believe the tax would be effective, which confirms what [Dresner et al. \(2006b\)](#) find with focus groups in the UK. Surveying Norwegian people, [Kallbekken & Sælen \(2011\)](#) shows that self-interest matters for acceptance, but less than concerns for environmental effectiveness or distributional effects.

In the present paper, we also study how these three motives affect acceptance. We contribute to the literature by providing evidence for causal effects where past studies essentially show correlations, often relying on proxies such as fuel consumption to proxy self-interest (e.g. [Thalmann, 2004](#); [Kallbekken & Sælen, 2011](#)). On the contrary, we do not assume that people are fully rational nor have perfect information. Thus, our methodology allows disentangling erroneous beliefs from *pure* effects of preferences. The paper also quantifies biases regarding the costs of the carbon tax. To our knowledge, this study is the first to compare subjective beliefs about the private cost of the policy and objective data using micro-simulation, showing that 89% of people overestimate their private costs. We show evidence that these biases do not only explain the policy rejection, but also follow from it through motivated reasoning ([Kunda, 1990](#)). Another contribution of this paper is to show the persistence of people’s beliefs over carbon tax policies, and the asymmetry and further pessimistic bias in their revision. We provide evidence on how these biases translate in attitudes towards policies, which echoes recent advances in the literature on beliefs’ formation where beliefs enter directly utility (e.g. [Bénabou & Tirole, 2002](#)), leading to a selective processing of new information ([Eil & Rao, 2011](#); [Sharot et al., 2011](#)).

The rest of the paper is organized as follows. In section 2, we describe our survey and other data sources. In section 3, we compare subjective perceptions to objective data, and measure the bias regarding the impacts of carbon taxation. In section 4, we highlight new biases in the way individuals revise these beliefs. In section 5, we estimate the effects on ac-

85 ceptance of rectifying biased beliefs. Section 6 concludes. Further results and methodological complements are reported in Appendix.

2 Survey and data

2.1 Our survey, “Beliefs & climate policies”

2.1.1 Survey data collection

90 The 3002 responses were collected in February and March 2019 through the survey company Bilendi. This company maintains a panel of French respondents whom they can email with survey links. Respondents are paid 3€ if they fully complete the survey. The respondents who choose to respond are first channeled through some screening questions that ensure that the final sample is representative along six socio-demographic characteristics: gender, age (5
95 brackets), education (4), socio-professional category (8), size of town (5) and region (9). The quotas are relaxed by 5% to 10% relative to actual proportions. Table 9 in Appendix A shows that our sample is still extremely representative. Nonetheless, observations are weighted to correct small differences between sample and population proportions. The median time for completion of the survey was 19 minutes. We made sure that all questions requiring some
100 concentration were in the first half of the survey.

2.1.2 The survey

The full survey in French can be seen [on-line](#) while an English translation is provided in Appendix F.¹ The questionnaire contains several random branches and treatments that are independent from one another: Figure 1 presents in a diagram the sequence of treatments
105 (represented by ellipses) and questions (boxes).

[Figure 1 about here.]

¹preferences-pol.fr/doc_q.php#_e

Priming on environmental issues

Two blocks of information are randomly displayed or not: one on climate change and the other on particulate matter. This priming divides the sample in four groups, who receive either one block of information, the other, none or both of them. Climate change information includes temperature trends for long run future, worrying facts on current and expected impacts, and a claim that keeping global warming below 2 °C is technically feasible. Particulates information consists in the estimated impact on French mortality (48,000 deaths per year), life expectancy (9 months less), and the assertion that reducing fuel consumption would improve health. The time spent on each block is saved, and links to scientific references are provided to support the information.

Household characteristics

In addition to the quotas strata, socio-demographic characteristics include zip code, household structure, income of the respondent and of their household. Energetic characteristics contain questions that allow us to estimate the impact of a carbon tax increase on housing expenditures: surface of accommodation, heating type (collective or individual) and energy source; as well as on transport expenditures: number of vehicles, type(s) of fuel, distance traveled last year and average fuel economy. The distributions of answers are much in-line with official statistics, as shown in Table 10 in Appendix A.

Partial tax reform

One partial tax reform is randomly allocated to the respondent: it consists in an increase of the carbon tax by 50€/tCO₂ specific either to heating fuel and gas, or to gasoline and diesel. Partial reforms on housing and transport feature the same string of questions. We first ask whether the respondent thinks their household would lose more or less than average in case of an unspecified increase in indirect taxation, both for the VAT tax and for the energy considered (housing or transport). Then, we specify in a new block that the revenues of the tax would be distributed equally to each adult, entailing a yearly transfer of 50€ (resp. 60€) for the partial tax on housing (resp. transport).² We also provide

²We chose to redistribute per adult instead of consumption unit to make the scheme more understandable.

We limited the number of beneficiaries to two per household to come closer to current welfare benefits that depend on the number of consumption units.

the price increases implied by the tax: +13% (resp. +15%) for gas (resp. domestic fuel) on the one hand, and +0.11€ (resp. +0.13€) for a liter of gasoline (resp. diesel) on the other. We make clear at the beginning that this survey is conducted by two researchers in social sciences, but we present the policy starting with “The government studies...” to capture the effect of distrust in government that could arise in the actual political process. Then, we ask the respondent whether their household would win, lose or be unaffected by the reform. Depending on their answer, we further ask them to estimate their expected gain (or loss) among 5 (or 6) intervals. The interval thresholds are tailored to each respondent, as they are computed in proportion of the number of consumption units of their household (as defined by Eurostat). Finally, respondents are asked to estimate their own elasticity as well as that of French people. To this end, we borrow the phrasing of Baranzini & Carattini (2017), and ask the expected decrease in consumption that would follow a 30% increase in the price of heating (or equivalently, an increase of 0.50€/L in fuel prices), among 5 brackets.

Tax & dividend

Initial perceptions Our main reform of interest is an increase by 50€/tCO₂ of the French carbon tax, that concerns both housing and transport.³ The revenues generated are redistributed equally, so that each adult receives a yearly lump sum compensation of 110€ (this figure was obtained using typical elasticities, see 2.2.1). After describing the reform, a first block of questions elicits the respondent’s perceptions. Their subjective gain is asked in the same manner as for the partial tax. The priming that “scientists agree that a carbon tax would be effective in reducing pollution” is randomly displayed or not before asking whether the reform would be effective in reducing pollution and fighting climate change. Then, respondents are asked to pick the categories of losers and winners with the reform. Finally, we ask: “Would you approve this reform?” and let the respondent choose between “Yes”, “No” and “PNR (I don’t know, I don’t want to answer)”. In the following, we say that

³Electricity is exempted from the French carbon tax “Contribution Climat Energie” (CCE) as it is already taxed on the EU-ETS, and has a low carbon content due to the large share of nuclear power.

a respondent *approves* a reform if they respond “Yes”, and that they *accept* the reform if they do *not* respond “No”. Given the low rates of approval, we study primarily the acceptance to get tighter confidence intervals. We also provide results for approval, and obtain similar findings.

160 **Opinion after knowledge** To test the persistence of beliefs and measure the importance of self-interest and fairness motives in the acceptance of the reform, we provide some information on the effect of the reform. To a random half of the sample, we explain that “this reform would increase the purchasing power of the poorest households and decrease that of the richest, who consume more energy”. To two-thirds of the respondents (the remaining half
165 plus one third of the respondent with that priming on *progressivity*), we tell that: “In five cases over six, a household with your characteristics would [win/lose] through the reform. (The characteristics taken into account are: heating using [energy source] for an accommodation of [surface] m²; [distance] km traveled with an average consumption of [fuel economy] L for 100 km.)”. Indeed, section 2.2.2 shows that we estimate correctly if a household wins
170 or lose in 83% of cases.

As most respondents do not believe the claim that the reform was progressive, we ask to the second half of the sample whether they think it is, to analyze the effects of priming on compliant respondents. We also ask again the winning category (i.e. if the respondent’s household would win, lose or be unaffected by the reform) and the approval to the reform.
175 Finally, we let the respondent pick the reasons why this reform seems beneficial, and undesirable. We report these results in a companion paper, [Douenne & Fabre \(2019\)](#), where we also study the socio-demographic determinants for approval.

Tax & targeted dividend In this block, we ask for the winning category and for the approval of four alternative reforms. Each respondent deals with just one of them, which
180 differs from the main reform only in the way revenues are recycled. Here, the payments, still equal among recipients, are targeted to adults whose income is below some threshold. The four thresholds correspond to the bottom 20%, 30%, 40% and 50% of the income distribu-

tion. They are computed using inflated deciles of individual income from the *Enquête sur les Revenus Socio-Fiscaux* (ERFS 2014) produced by Insee (the French national statistics bureau).⁴ Respondents whose income lies between two thresholds are allocated randomly to a reform featuring one of them. When the income is close to only one threshold (i.e. when its percentile in the distribution is below 20 or within [50; 70]), the allocated reform corresponds to that one. When the respondent’s income is above 2220€/month (which is the 70th. percentile), the reform they face is determined by the income of the households’ second adult. Finally, when both (or the only one) adults in the household earn more than 2220€/month, their reform is allocated randomly between the four variants. Table 1 describes the targeted reforms and the proportion of respondents allocated to each of them, along with the proportion one would expect from the *ERFS*. The two sets of figures match almost perfectly, indicating that our sample is representative along the income dimension.

[Table 1 about here.]

Other questions We do not detail the other questions of the survey, because we analyze them in a companion paper, [Douenne & Fabre \(2019\)](#). We scrutinize opinions on environmental policies, including other ways to recycle the revenues of a carbon tax. We measure the knowledge and perceptions of climate change; ask some specific questions over shale gas, over the influence of climate change on the choice to give birth and on willingness to change one’s lifestyle. We study the use, availability and satisfaction with public transportation and active mobility. We ask political preferences, including the positioning in relation to the Yellow Vests. Finally, we let the respondent express any comment in a text box.

2.1.3 Ensuring data quality

We took several steps to ensure the best possible data quality. We excluded the 4% of respondents who spend less than 7 minutes on the full survey. We confirm that response time

⁴Incomes entitled to the household rather to its members, such as certain welfare benefits, are divided equally among the two oldest adults of the household.

is not significantly correlated with our variables of interest (such as approval or subjective gain). In order to screen out inattentive respondents, a test of quality of the responses was inserted, which asked to select “A little” on a Likert scale. The 9% of respondents who failed the test were also excluded from our final sample of 3002 respondents. Also, when the questions about a reform were spread over different pages, we recalled the details of the reform on each new page. We checked for careless or strange answers on numerical questions, such as income or the size of the household. We flagged 10 respondents with aberrant answers to the size of the household (and capped it to 12) and up to 273 respondents with inconsistent answers, such as a household income smaller than individual income, or a fuel economy higher than 90 liters per 100 km. An examination of these answers shows no significant correlation with our variables of interest, and suggests that these respondents have simply mistaken the question. Among these inconsistent answers, 58 respondents have answered more than 10,000€ as their monthly income (despite the word “monthly” being in bold and underlined), with answers in the typical range of French incomes. We have divided these figures by 12.

2.1.4 Notations

To improve the understanding of our specifications in the regression Tables, we adopt consistent notations throughout the paper. For questions where possible answers are “Yes”/“No”/“PNR”, we define two kinds of dummy variables: the default ones correspond to *not* “No” answers, while we put a dot on dummy variables for “Yes”. For example, acceptance is denoted A while approval is denoted \dot{A} . Furthermore, for questions that are asked several times, namely acceptance and winning category, an exponent is added to specify the step at which the question is asked. Table 2 describes these exponents as well as the notations corresponding to the different notions of gain that we use. Uppercase is used for binary and lowercase for continuous variables, Greek letters denote objective notions, with a hat for our estimation of gains and without for the true (unknown) ones. To give another example, the broad notion of self-interest at the initial step, i.e. the belief that one does not lose, is denoted G^I , and the strict belief that one wins at Tax & Targeted dividend is denoted \dot{G}^T .

[Table 2 about here.]

2.2 Official households surveys

2.2.1 Eliciting objective aggregates and distributions

One of the goals of the paper is to compare respondents' perceptions with actual impact of a carbon tax on households' purchasing power. For this purpose, we use the database constructed by Douenne (2018) whose objective was to estimate the distributive effects of a carbon tax for French households. This database matches two households surveys produced by Insee: the consumer survey *Budget de Famille* (BdF 2011) and the transport survey *Enquête Nationale Transports et Déplacements* (ENTD 2008).

Consumer survey “Budget de Famille” The consumer survey *Budget de Famille* (BdF 2011) is a household survey providing information over all households' revenues and expenditures, together with many socio-demographic characteristics. It was conducted in several waves from October 2010 to September 2011, over a representative sample of 10,342 French households. The main advantage of BdF when studying the incidence of carbon taxation is that expenditures in both housing and transport energies are reported. Consumption of housing energies is taken from households' bills, and for most other goods respondents report their expenditures over the past week. As explained in Douenne (2018), this data collection is problematic when looking at the incidence of a tax on transport energies, as short-run fluctuations in consumption lead to overestimate the variation in expenditures.

Transport survey “Enquête Nationale Transports et Déplacements” To overcome this limitation, BdF is matched with the transport survey *Enquête Nationale Transports et Déplacements* (ENTD 2008). ENTD was conducted in several waves from April 2007 to April 2008, over a representative sample of 20,178 French households. It provides information on households characteristics, their vehicle fleet and use over the past week, but most importantly it gives information on annual distances travelled with these vehicles. This last

information enables to recover the distribution of transport fuel expenditures without over-
estimating its spread. Such a matching is not necessary for housing energies as these already
represent consumption over long periods in BdF. Finally, data from National Accounts are
used to make the data representative of the year 2017.

Computing tax incidence and revenues From this dataset, we are able to compute
the distribution of households' *objective* net gains in purchasing power after the policies
proposed. We also use it to determine the total tax revenue to be redistributed lump sum.
The formulas used for these computations are given in Appendix B.1. Our computations use
typical elasticities found in the literature on French households: -0.4 for transport and -0.2
for housing, as well as an incidence borne at 80% by consumers.⁵

2.2.2 Computing households expected net gains

Simulating expected gains for the feedback Households are asked about yearly dis-
tance traveled and average fuel consumption of their private vehicles. From this information,
it is then possible to compute the expected cost of a carbon tax on transport fuels. For
housing energies, the collected information does not enable such simple calculations. In-
stead, we use the housing survey *Enquête Logement* (EL 2013) that provides information
on households expenditures in housing energies as well as many demographic and energetic
characteristics. The survey was conducted between June 2013 and June 2014 over a sample
of 27,137 households in metropolitan France. This enables to compute the expected cost
from the carbon tax on housing energies, and regress it on households' characteristics. The
results are provided in Appendix B.2, where they are shown to be as least as accurate to
the ones obtained from alternative prediction methods and specifications. The distribution
of housing energy expenditures is very comparable to the one of BdF. Adding this estimated
cost to the one simulated for transport energies, subtracting the amount received in lump
sum transfers, and dividing by the number of consumption units, we estimate the impact of

⁵These values correspond to the short run uncompensated price elasticities estimated by Douenne (2018),
and are in line with previous findings on French households (e.g. Clerc & Marcus, 2009; Bureau, 2011).

the policy on the purchasing power of each household.

285 **Assessing feedback’s accuracy** The previous estimation could have also been conducted with BdF data. Still, running this estimation on the housing survey enables to test the accuracy of our prediction out-of-sample: for each household in BdF, we compute the impact of the policy on their purchasing power and compare it to the prediction from our simulations. Figure 7 in Appendix C.2 shows how the probability that our prediction is correct depends on
290 objective gains. For five households out of six, we correctly predict whether their purchasing power would increase or decrease through the policy. This ratio is made symmetrical: among households in BdF predicted to win, 83.4% were actual winners, while among those predicted to lose, 83.4% were actual losers. Since the simulation and its test are done on different households, there is no concern for over-fitting: the probability that our feedback is correct
295 is not overestimated. Assuming that the characteristics reported by our respondents are correct, there is no reason to believe that the probability of error is higher or lower when simulations are applied to our survey respondents.

3 Perceptions

3.1 Self-interest

300 **Over-estimation of policy costs** Figure 2 plots the kernel density of expected net gains for objective data from BdF, and subjective beliefs from our survey. Figure 3 compares the CDF of objective vs. subjective net gains.⁶ It clearly appears from these figures that on average, respondents overestimate the cost of the policy, even in the extreme case of perfectly inelastic expenditures. This result holds both for the carbon tax and for partial

⁶The subjective intervals are translated into numerical values, assuming that the distribution within each interval are the same than for BdF data. Within each bin, we draw values that match the actual distribution for the PDF, while we simply take the actual average for the CDF. Among the several methods that we tried to assign numerical values, all realistic ones yield identical results, and we find an overestimation of policy costs even in the most conservative one (taking the maximal bounds of intervals).

305 carbon taxes on transports and housing energies. The average net gains from the carbon tax on transport, housing and both, are respectively 18€ per consumption unit (c.u.), 6€ per c.u. and 24€ per c.u. from BdF data. Extrapolating from our survey, we instead find average subjective net gains of respectively −61€, −43€ and −89€. The median gap of 116€ between objective and subjective gains indicates a substantial bias towards loss from typical
 310 respondents. This bias is common, as we find that 89% of respondents underestimate their gain of purchasing power using our households’ specific estimation. This proportion remains as high as 77 % when assuming inelastic expenditures, which provides a lower bound on the share who underestimate their net gain in utility. In other words, while 70% of households should benefit (in monetary terms) from the compensated carbon tax, only 14% think they
 315 would (and 22% see themselves unaffected).⁷

[Figure 2 about here.]

[Figure 3 about here.]

Heterogeneity in bias In order to characterize profiles of individuals more likely to mis-perceive their gains, we regress mis-perception over many respondents’ characteristics. Mis-
 320 perception is defined as a gap between objectively estimated and subjective net gains beyond 110€ per c.u., because our estimation differs from true objective gain by more than 110€ in only 5% of cases. This definition insures that the 55% of respondents with a mis-perception have in fact a large bias. Besides, other definitions for the bias yield very similar results. The results given in Table 3 show that mis-perception is largely idiosyncratic: controlling for
 325 a large set of variables⁸ (column 1), the R^2 remains small (0.06). Still, we identify several variables having a significant effect on mis-perception. In particular, females appear to mis-perceive their gain 4 percentage points (p.p.) more on average, other things equal. Ecologists on the other hand are about 6 p.p. less likely to display a large bias. Interestingly, while the

⁷For transport and housing energy taxes, the objective proportions of winners are very similar at respectively 74% and 67%, while the subjective shares are 16% and 17% (with 22% and 30% of unaffected).

⁸The control variables used throughout the paper are described in Appendix E.

standard left/right political leaning has no significant effect, the position towards the Yellow
 330 Vests appears as the most critical determinant in mis-perception. Relative to respondents
 who declared to be opposed to the movement, those who declared to “understand”, “support”
 or “be part” of it are more likely to mis-perceive their gains. This effect is increasing with the
 degree of adhesion, up to 20 p.p. for individuals who declared to be part of the movement.
 These last two results (difference with ecologists and supporters of Yellow Vests) suggest that
 335 mis-perceptions could be explained by “motivated reasoning” (Kunda, 1990), a tendency to
 form beliefs in accordance with preferences. This hypothesis is supported by the results from
 column (3), where position towards the policy are included: people who approve the policy
 are 28 p.p. less likely to mis-perceive their gains relative to those who do not accept it, and
 10 p.p. less relative to those who do not know. We can think that the degree of support
 340 of the policy is what determines most of the bias (explaining e.g. why *ecologist* loses its
 explanatory power when we control for the support), and that the Yellow Vests variables
 remain significant only because they capture different *degrees* of rejection of the tax (which
 our Yes/No question cannot do).

Overall, typical biases are large and closely related to one’s convictions. However, causal-
 345 ity between beliefs and rejection can go in both directions. Section 4 provides evidence that
 some people think they lose because they oppose the tax, while section 5 shows that perceived
 outcomes strongly influences approval.

[Table 3 about here.]

3.2 Environmental effectiveness

350 A well established result in the literature on the acceptability of climate policies is the
 perceived ineffectiveness of Pigouvian instruments (e.g. Dresner et al., 2006a; Kallbekken
 et al., 2011; Baranzini & Carattini, 2017). In particular, people do not see carbon taxes
 as effective to fight climate change. Our findings confirm this result: among our survey
 respondents, only 17% answered “Yes” when asked whether Tax & dividend would be effective

in reducing pollution and fighting climate change, 66% answered “No”, 18% that they did not know.

An explanation sometimes encountered to explain perceptions of ineffectiveness is that most people believe that energy consumption is little elastic (Kallbekken & Sælen, 2011; Carattini et al., 2018). To test this hypothesis, we regress a binary variable E equal to 0 if the respondent does not perceive the policy as environmentally effective and 1 otherwise, on their subjective price elasticity for French people. As respondents were randomly assigned to transport or housing, we run a separate regression for both types of energies. Table 12 in Appendix C.3 reports results with and without control variables. They all consistently indicate that a respondent anticipating an elasticity of -1 is (on average) 6 p.p. more likely to perceive the policy as effective than one anticipating no elasticity. Although significant, the magnitude of the effect is modest, showing that the perceived ineffectiveness of tax instruments should not be reduced to small subjective elasticities. Indeed, among respondents who perceive the policy as environmentally ineffective, almost half anticipate responses to price signals larger than the literature.⁹

A more plausible explanation for perceived ineffectiveness is that people disbelieve that the policy would be sufficient to affect *substantially* pollution and climate change. Taking respondents’ average anticipated elasticities for transport and housing energies, the tax should reduce French greenhouse gas (GhG) emissions by 5.7 Mt of CO₂ equivalent (CO₂e) each year, according to simulation from BdF data. This reduction corresponds to 0.8% of French annual emissions, 0.01% of global ones, and does not suffice to reach the official objective of a decrease in emissions by 1.8% *each year* to reach carbon neutrality in 2050.¹⁰ Thus, although

⁹Overall, average subjective elasticities are close to these estimates for transports (at -0.45) and somewhat overestimated for housing (-0.43). Among those who declared that the policy was not effective, 45% (resp. 43%) anticipated an aggregate elasticity at or below -0.5 for housing (resp. for transport), while elasticities obtained from the literature are around -0.2 for housing and -0.4 for transport.

¹⁰In 2014, French GhG consumption based emissions were equal to 712 MtCO₂e (CGDD, 2019). 2017 global emissions were 53.5 GtCO₂e (UNEP, 2018). Alterea evaluates at 1.8% each year the reduction required to meet France National Low-Carbon Strategy (CGDD, 2015).

respondents do anticipate responses to price incentives, an interpretation of our results is that they do not perceive a 50€/tCO₂ national carbon tax as a proportionate reaction to climate change.

3.3 Progressivity

It is often argued that a critical barrier to acceptance of carbon taxation is its perceived distributional impact, in particular the higher burden imposed on lower income households (Bristow et al., 2010; Brannlund & Persson, 2012; Gevrek & Uyduranoglu, 2015). A large literature has shown that carbon taxation alone is regressive (Poterba, 1991; Metcalf, 1999; Grainger & Kolstad, 2010), meaning that it is more costly for poorer households as a share of their resources. However, it has also been shown that redistributing its revenue through uniform lump sum transfers — a mechanism known as flat-recycling — can make the policy progressive (West & Williams, 2004; Bento et al., 2009; Williams et al., 2015), including for France (Bureau, 2011; Douenne, 2018). Figure 6 in Appendix B.3 displays the average net gain by income decile for Tax & dividend. It clearly appears from this figure that lower income households would gain more than richer households, both in relative and in absolute terms. Yet, only 19% of respondents think the policy would benefit poorest households, against 60% who declare it would not, and 21% who do not know. These results show that beliefs about the distributive effects of carbon taxation are biased, which was not shown in previous studies.

4 Are beliefs persistent?

The previous section has shown that people’s low acceptance of Tax & dividend coincided with biased beliefs about the properties of the scheme. As knowledge about these properties has been shown decisive for acceptance (Carattini et al., 2018), it is important to assess to what extent beliefs are persistent. In the following, we test respondents’ reaction to information about their gains, environmental effectiveness and progressivity. If their biased

views simply reflect a lack of knowledge, we should expect them to revise their beliefs after new information is provided. We show that on average people update less than they should, indicating persistent biased beliefs. Moreover, we show that revisions are asymmetric and
405 strongly biased towards pessimism.

4.1 Self-interest

Conservatism and pessimism After telling respondents that given their characteristics, they have 5 chances over 6 to “win” or “lose” from the policy, we observe that only 39% of them agree with our feedback ($G^F = \hat{\Gamma}$), far from the 83% expected for a correct update. This result
410 is consistent with findings of the literature that people tend to update like “conservative” Bayesians (Edwards, 1968). The full transition matrices of people’s beliefs are given in Tables 13 and 14 in Appendix C.2. More concisely, Table 4 reports the share of respondents whose beliefs after being informed are aligned with our feedback, with the corresponding 95% binomial confidence intervals. It shows that, for the 24% of individuals who receive a
415 “lose” feedback ($\hat{\Gamma} = 0$), the *ex post* belief is on average consistent with a perfect updating. If anything, these people would rather tend to agree *too much* with our noisy signal, especially when excluding people who initially consider themselves as unaffected (i.e. focusing on $g^I \neq 0$), for whom 83% does not lie in the 95% confidence interval.¹¹ The observed conservatism on the whole sample therefore comes from respondents who receive a “win” feedback ($\hat{\Gamma} =$
420 1). Among the 60% of respondents who initially thought they would lose in this group, only 12% endorse the “win” feedback. This is in sharp contrast with the respondents who initially thought they would win and receive a “lose” feedback, since 82% of them endorse our prediction. Thus, pessimistic beliefs are persistent, but optimistic ones are not.

[Table 4 about here.]

425 Table 15 in Appendix C.2 conducts the same analysis for the 28% of respondents whose gain is largely positive or largely negative, i.e. above 110€ per c.u. in absolute terms.

¹¹We observe that respondents revise less their belief when they feel “unaffected”, indicating that some of them may have misunderstood this category for “I don’t know”.

For such respondents, our out-of-sample prediction of winning category is correct in 99% of cases, as can be seen on Figure 7 in Appendix C.2. The alignments with our feedback are similar for the whole sample and for these respondents for whom we are sure to make a correct prediction. The similarity of alignments for different prediction accuracy rules out the possibility that some respondents do not update because their private information would be *truly* more accurate than our prediction.

There are several ways to rationalize the conservatism and pessimism we observe. The simplest is that respondents perceive our information as biased. They may think we wrongly estimate their likelihood to win, and that we are too optimistic. A second interpretation is that they give too much value to their private information relative to the base rate one, a phenomenon known as base rate neglect (Grether, 1980). That is to say, pessimistic winners might be over-confident in seeing themselves as specific so that they partly discard the new information, e.g. by thinking they are part of the one sixth for whom our prediction is erroneous. Another explanation is that uncertainty makes people see their possible gains as a distribution. Then, instead of reporting the average of this distribution, people subject to risk-aversion would reason with conservative estimates for their gains, even more so if they believe that this survey can influence policy makers. In the end, these interpretations are of course not mutually exclusive, and empirically not distinguishable as they all translate in too much pessimism in the revision of their beliefs.

Determinants of correct updating To handle the notion of *correct updating*, we define a variable U which equals +1 if the respondent adopts a feedback that invalidates their initial belief, -1 if they update against the feedback that confirms it, or 0 if they do not update. Over the sub-sample of respondents who should have updated because their initial winning category is not aligned with our feedback, we regress the *correct updating* U over the initial belief not to lose G^I and a vector of characteristics \mathbf{C} :

$$U_i = \delta_0 + \beta_U G_i^I + \beta_{\mathbf{C}} \mathbf{C} + \epsilon_i \mid \dot{G}_i^I = -\hat{\Gamma}_i, \quad (1)$$

The high value for β_U reported in column (1) of Table 5 again proves that, among those who should have updated, those who initially think they win (the optimistic losers) update significantly more correctly than those who do not (the pessimistic winners). Many other
455 specifications have been tested, depending on how unaffected are treated and whether controls are included or not, or with the winning category after the feedback as covariate, and they all confirm a win/lose asymmetry in updating.

[Table 5 about here.]

Beyond this asymmetry, column (2) shows that some respondents’ characteristics are
460 correlated with correct updating. Relative to unemployed and inactive people, retired, active and students update more correctly, the latter being 25 p.p. more likely to correctly revise their beliefs when invalidated than unemployed and inactive. Similarly to perceptions of net gains, position towards the Yellow Vests is significantly correlated with correct updating. The magnitude of this effect is large, as people who are part of the movement are 17 p.p. less likely
465 to correctly update than people who oppose it. This can be linked to the higher distrust of the Yellow Vests towards the government, documented in [Algan et al. \(2019\)](#), that could apply to information provided by researchers regarding policies. Column (3) includes disapproval as a covariate: it indicates that, as for the initial bias in subjective gains, disapproving the reform is associated with a less correct update by 16 p.p. and partly explains the effect of
470 the Yellow Vests.

Explanatory mechanisms The previous results suggest that conservatism in beliefs revision does not simply follows from people’s cognitive difficulties when dealing with Bayes’ rule. The determinants identified (“win” vs. “lose” feedback, attitude towards the policy and the Yellow Vests) rather indicate that beliefs formation and revision are intrinsically linked
475 to preferences, a mechanism known as “motivated reasoning” in the literature ([Kunda, 1990](#)). Closely related is the well documented “confirmation bias”, the tendency to weigh information differently depending on whether it confirms or not a prior belief. More recently, studies have also shown evidence of a “good news – bad news effect” ([Eil & Rao, 2011](#); [Sharot et al.,](#)

2011), meaning that people tend to give more weight to information that satisfies their ego

480 or self-interest. Our results go *a priori* in the opposite direction since people discard what we could consider “positive” news ($\hat{\Gamma} = 1$) but not negative ones ($\hat{\Gamma} = 0$). Still, this effect is consistent with motivated reasoning as the lack of update has been shown much stronger for people who disapprove the policy and for supporters of the Yellow Vests. Thus, people’s positioning does not only bias their initial perception about the policy, but also their processing
485 of new information about it.

4.2 Environmental effectiveness

Table 16 in Appendix C.3 reports the effect of displaying relevant information on the belief that Tax & dividend is environmentally effective. The effect of reporting a scientific consensus on environmental effectiveness (E) is positive and statistically significant, but its magnitude
490 — around 5 p.p. — seems modest given that the question immediately follows the priming. The effects of information on climate change (CC) or particulates (PM) are smaller, and only CC is significant, which is understandable as they were displayed at the very beginning of the survey and do not mention any environmental policy. As suggested by Millner & Ollivier (2016), given the complexity of the mechanisms at play, drawing a causal link between causes
495 and consequences of environmental problems requires considerable cognitive efforts, making it difficult to convince about effectiveness of policies that decentralize efforts to tackle pollution. Finally, we observe that our primings have no significant effect on beliefs over causes and consequences of climate change. Overall, these primings appear insufficient to change most people’s mind about climate change and carbon tax effectiveness.

500 4.3 Progressivity

Table 17 in Appendix C.4 shows the absence of effect of explaining that Tax & dividend is progressive on perceived progressivity: the correlation between the two is close to 0 (at -0.006) and even has an unexpected negative sign. Column (2) of the same table clarifies why our treatment does not change the overall share of people who think the policy is

505 regressive: those who have a large bias in their perception of gains are in fact *more* prone to perceive *regressivity* once provided the information, by 13 p.p. This result may be a manifestation of the boomerang effect with people inclined to motivated reasoning: indeed, [Hovland et al. \(1953\)](#) showed that when someone is pressured to make a certain choice, psychological reactance (theorized by [Brehm, 1966](#)) can cause them to resist this pressure by
510 adopting an opposite alternative. Although the effect on those without a large bias is not significant, providing them the information is associated with a lower perceived regressivity by 5 p.p. A possible explanation for the strong belief in regressivity is that people view the tax as regressive (relative to income) and the transfer as neutral (in absolute values), and mistakenly conclude that their combination is regressive. Anyhow, without a deep explanation of the
515 underlying mechanisms, the progressivity of the policy remains unintuitive to most people, and we cannot convince them easily.

5 Motives for acceptance

Our results clearly indicate that, as of today, a carbon tax is unlikely to be accepted in France. However, we have also shown that people largely display wrong perceptions about the true
520 effects of the policy. Most of them overestimate the negative impact on their purchasing power, think that the policy is regressive, and do not see it as environmentally effective. In this section, we examine to what extent the low acceptance rate reflects true preferences or wrong perceptions. The question we address is whether correcting biased beliefs would be sufficient for a carbon tax to be accepted.

525 5.1 Self-interest

Identification challenge While three quarters of the respondents are expected to win from Tax & dividend, 62% of these winners consider that they would not win and disapprove the policy. We want to estimate to what extent knowing they would win would lead them to approve the reform. Because respondents thinking they would win might differ in many

530 respects from those thinking they would not, we cannot simply regress approval on perception of winning.

Main identification strategy In order to identify the effect *ceteris paribus* of self-interest on acceptance, we exploit exogenous variations in gains and losses. To do so, we consider Tax & targeted dividend, where respondents are randomly affected to a compensation scheme to which they are eligible or not (see section 2.1.2). Our methodology mixes a random discontinuity design (RDD) and an instrumental variable (IV) strategy. Let us denote by $I_{1,i}$ respondent's i income, and by $I_{2,i}$ the income of the second adult of their household if their is one, which we control for with a dummy variable S_i equal to 1 when there is a single adult. Let $T_{1,i}$ and $T_{2,i}$ be two binary variables indicating whether these individuals would be eligible to the transfer.¹² We also denote by G_i^T a dummy variable equal to 0 if respondent i thinks they would lose from Tax & targeted dividend, and 1 otherwise. Similarly, A_i^T is a dummy variable equal to 0 if respondent i disapproves this policy and 1 otherwise. We can then write a two stage least-square model, with the following first stage equation:

$$G_i^T = \alpha_0 + \alpha_1 T_{1,i} + \alpha_2 T_{2,i} + \alpha_c c_i + \alpha_S S_i + \sum_{j=1}^2 (\alpha_{1,j} I_{1,i}^j + \alpha_{2,j} I_{2,i}^j) + \eta_i \quad (2)$$

where second order terms for income bring more flexibility. We precise that eligibility is defined using income thresholds c_i that are randomly allocated to households (see section 2.1.2) and introduced as fixed effects to control for threshold specific preferences. Formally, we define eligibility of adult $k \in \{1; 2\}$ as:

$$T_{k,i} = \begin{cases} 0, & \text{if } I_{k,i} > c_i \\ 1, & \text{otherwise} \end{cases} \quad (3)$$

¹²As explained in section 2.1.2, we explicitly limit the number of beneficiaries to two by household.

Finally, the second stage writes:

$$A_i^T = \beta_0 + \beta_1 \widehat{G}_i^T + \beta_c c_i + \beta_S S_i + \sum_{j=1}^2 (\beta_{1,j} I_{1,i}^j + \beta_{2,j} I_{2,i}^j) + \epsilon_i \quad (4)$$

where \widehat{G}_i^T denotes the fitted value of G_i^T from the first stage regression. As can be seen from
 550 first stage results in Appendix D.1, eligibility of both respondents and households' second
 adults are positively correlated with beliefs of winning, so both instruments are relevant. The
 exclusion restriction states that conditional on income, being eligible affects approval solely
 through beliefs of winning. The RDD procedure employed in the first stage ensures that this
 is the case: conditional on income, eligibility is random, and it should affect acceptance only
 555 through self-interest.

Alternative specifications for robustness To further ensure the robustness of the re-
 sults, we estimate several alternative specifications. First, we run the same RDD + IV design
 adding control variables (specification 2). In particular, we control for initial acceptance of
 Tax & dividend as this should explain most of the variation in the dependent variable. Sec-
 560 ond, we compare our results with a simple OLS where we control for relevant variables (3).
 Third, we use a logit model (4) to ensure that imposing linearity does not bias the results.
 Finally, we exploit a methodology similar to the main specification but applied to the feed-
 back, without (5) and with (6) control variables. Indeed, as our estimation of gains for
 this feedback is a continuous variable $\widehat{\gamma}$, but the feedback itself is a binary variable $\widehat{\Gamma}$, we
 565 run an RDD to predict the belief of winning after feedback G^F . We then exploit variations
 around the threshold of zero net gain (which are random conditional on net gain) to explain
 acceptance A^F . This alternative two stage least square writes:

$$G_i^F = \alpha_0 + \alpha_1 \widehat{\Gamma}_i + \sum_{j=1}^2 \alpha_{1,j} (\widehat{\gamma}_i)^j + \eta_i \quad (5)$$

$$A_i^F = \beta_0 + \beta_1 \widehat{G}_i^F + \sum_{j=1}^2 \beta_{1,j} (\widehat{\gamma}_i)^j + \epsilon_i \quad (6)$$

where \hat{G}_i^F denotes the fitted value of G_i^F from the first stage regression. The identification assumption of this second IV states that conditional on estimated net gains ($\hat{\gamma}$), receiving a win feedback ($\hat{\Gamma} = 1$) affects approval solely through self-interest. Finally, we also investigate alternative versions of the previous models where we estimate the effect to “win” instead of “not to lose”, and on “approval” instead of “acceptance”.

Results First stage regression results are given in Appendix D.1. The effective F-Statistics (Olea & Pflueger, 2013) range from 38 to 58, indicating that both targeted transfers and feedback are strong instruments. Table 6 provides the second stage results for the six main specifications, and additional specifications can be found in Appendix D.2. Overall, the estimated effects of self-interest indicate that believing not to lose increases acceptance by about 50 p.p. The results obtained for the local average treatment effect (LATE) on compliers in IV regressions — i.e. on people who recognize they would not lose because of the treatment — are significantly higher than for the average treatment effect (ATE) estimated with OLS (57 vs. 44 p.p. for Tax & targeted dividend). Given the wide set of control variables used, and in particular our powerful control A^I , one can be rather confident that the OLS estimate is unbiased, and the difference due to the specificity of compliers in the LATE. This explanation holds for both the targeted scheme and acceptance after feedback, and is supported by the findings of section 4.1 for the latter. Indeed, as respondents most likely to revise their beliefs after a “win” feedback are also more in favor of the tax, the IV coefficient for compliers is logically higher than the point estimate found with OLS. The comparisons of columns 1 with 2, and 5 with 6 show that adding control variables does not significantly affect the coefficient for Tax & targeted dividend, but does for acceptance after feedback, where the controls seem to capture part of the specificity of compliers. Overall, both methods yield similar effects: 57 p.p. with targeted transfers and 52 p.p. with the feedback. Finally, results from the logit regression (4) confirm that the assumptions of the linear probability model (LPM) do not bias the results.¹³

¹³Separation occurs in logistic regressions for self-interest and effectiveness. We made sure this does not lead to biased coefficients by conducting likelihood ratio tests and by running penalized regressions (Firth,

[Table 6 about here.]

By isolating *beliefs* about self-interest *ceteris paribus*, we showed that this motive has a large effect on carbon tax acceptance. This result confirms previous findings of the literature (Stern et al., 1993; Thalmann, 2004; Baranzini & Carattini, 2017), but contrasts with the results of Kallbekken & Sælen (2011) who found that self-interest plays a limited role in Norway. Their different result could come from their methodological approach that relies on proxies to capture self-interest in regressions, or on differences between preferences of French and Norwegian people.

5.2 Environmental effectiveness

Main identification strategy One of the strongest barriers to carbon tax implementation is a widespread perception of its environmental ineffectiveness. Our objective is therefore to assess to what extent learning about the environmental benefits of the tax could increase acceptance. To identify this effect, we estimate a two-stage least squares (2SLS) where the first stage uses random information to explain beliefs about environmental effectiveness, while the second stage regresses acceptance on the fitted exogenous variations in these beliefs. Because information on particulate matter (Z_{PM}) are poorly correlated with beliefs of effectiveness, we restrict the set of instruments to our primings on the scientific consensus (Z_E) and climate change (Z_{CC}). As discussed in section 4.2, these instruments are significantly related to our endogenous variable, yet potentially weak as our primings do not have a large effect on people’s beliefs. If we denote E a dummy variable equal to 0 if the respondents thinks the policy is not environmentally effective and 1 otherwise, we can write a 2SLS model as follows:

$$E_i = \alpha_0 + \alpha_1 Z_{E,i} + \alpha_2 Z_{CC,i} + \alpha_{\mathbf{C}} \mathbf{C}_i + \eta_i \quad (7)$$

$$A_i^I = \beta_0 + \beta_1 \hat{E}_i + \beta_{\mathbf{C}} \mathbf{C}_i + \epsilon_i \quad (8)$$

1993; Heinze & Ploner, 2003).

where \hat{E}_i denotes the fitted value of E_i from the first stage regression, and \mathbf{C} a vector of characteristics.

Alternative specifications for robustness checks To ensure the robustness of our results, we estimate the previous 2SLS with control variables (1). Acknowledging that our primings could affect acceptance motives other than effectiveness alone, this potential bias should disappear when controlling for many variables including other motives. In addition, we estimate an OLS (2) model to compare the LATE of the first specifications with an ATE, and a logit model (3) to check the robustness of assumptions underlying the linear probability model. Finally, we also estimate two modified versions of our main specifications, where we switch from broad to strict definitions for environmental effectiveness (4) and for tax approval (5).

Results The first stage regressions results can be found in Appendix D.1. Because of the relatively modest responses to our primings, the instruments are rather weak (effective F-statistic of 6 in column 1), a problem that is alleviated in the case of strict definitions (11 in columns 4 and 5). Given the exogeneity of our instruments, the only concern is a potential bias towards OLS, which would entail too conservative estimates in our case. Table 7 reports the results of the second stages. All specifications consistently indicate a strong positive effect of beliefs about environmental effectiveness on tax acceptance. Overall, the effects are statistically significant, and their size comparable to the one of self-interest, at 48 p.p. for our main IV regression (column 1). The LATE is again somewhat higher than the ATE estimated with OLS (2) — 48 vs. 39 p.p. — which is likely due to differences between compliers and other respondents: people who are most likely to change their mind following our information might also be more willing to accept the policy. Still, the coefficients obtained for the ATE remain large and indicate that beliefs over the policy’s environmental effectiveness are critical for acceptance. Results of the logit model close to the ones of OLS confirm that the LPM does not induce a bias in the estimation (3). Lastly, the effect is relatively close with the strict definition of the dependent variable — 42 p.p. in (5), showing that the coefficient is

not driven by a correlation between “PNR” responses to tax effectiveness and approval.

[Table 7 about here.]

645 The critical role found for beliefs about environmental effectiveness is in line with findings of the literature (Sælen & Kallbekken, 2011; Kallbekken & Sælen, 2011; Baranzini & Carattini, 2017), although previous studies did not properly identify a causal effect. Our results thus confirm that convincing people about the environmental effectiveness of carbon tax would largely increase acceptance of this instrument.

650 5.3 Progressivity

Identification challenge and strategies As informing respondents does not convince them that Tax & dividend is progressive (see section 4.3), we cannot identify the causal effect of understanding the progressivity on acceptance using an IV estimation. Thus, we estimate how belief in progressivity correlates with acceptance using simple OLS and logit
655 regressions. Controlling for many respondents’ characteristics and other acceptance motives, one can be confident that the effect of progressivity is properly isolated. We focus on the acceptance question *after knowledge*, i.e. after asking whether the reform is progressive or not.¹⁴ Table 8 presents the results of different regressions, depending on the set of controls and on the choice of variables. Columns (1)-(4) report regressions of acceptance on the
660 broad definition of motives of acceptance: answers *not* “No” to progressivity, effectiveness and *not* “lose” to winning category. On the contrary, columns (5)-(6) use strict definitions for both approval and the covariates, where only “Yes” (or “win”) answers activate the dummy variables.

Results On average, believing that the reform is *not regressive* is associated with a higher
665 *acceptance* rate by 56 p.p. (column 3), while believing it is *progressive* is associated with

¹⁴As self-interest and effectiveness were made salient from the *initial* questions, treating progressivity *after knowledge* is the only way to make results comparable across motives.

a higher *approval* rate by 48 p.p. (6). However, when one introduces other motives of acceptance and their interactions as covariates, with households characteristics as controls, one observes that the effect of progressivity *ceteris paribus* is lower. The marginal effect of progressivity at the sample mean — i.e. accounting for the average marginal effect of interaction terms — is 27 p.p., slightly lower than the marginal effect obtained for self-interest (40 p.p.) and environmental effectiveness (31 p.p.). The effect obtained for the latter motive is lower than the OLS estimate found in section 5.2, because here acceptance is taken at a later step in the survey and not right after asking about environmental effectiveness, making it less salient. Besides, one might worry that perceived progressivity would be hard to disentangle from beliefs over net gains, as the latter is influenced by the former for a given income. To address this dependency, we include the interaction between progressivity and income as a covariate (2, 5). Although the coefficient is negative, in accordance with intuition, the effect is low and not significant. Finally, using the strict definitions of beliefs and approval yields a smaller correlation (6) but similar results when accounting for relevant controls (5), showing that the effects are not driven by a correlation between “PNR” answers.

[Table 8 about here.]

These results show that progressivity is a motive for acceptance almost as determinant as self-interest and effectiveness. This concern for distributional effects is consistent with the findings of Kallbekken & Sælen (2011), Brannlund & Persson (2012) and Gevrek & Uyduranoglu (2015), but contrasts with the results of Baranzini & Carattini (2017), who found that among Genevan, the concern exists but does not affect acceptance of environmental policies.

5.4 Complementarity between motives

5.4.1 Combined effects

Table 8 (column 1) shows that the combined effect of the three motives together — i.e. adding up their coefficients and the ones of their interactions — is as high as 90 p.p., confirming that these motives are the critical beliefs needed to accept the policy, and that they complement

(rather than substitute) one another. Considering *approval* when respondents *do believe* that the policy is effective, progressive and satisfies their self-interest (5), the results are quite similar although it appears that the two altruistic motives are more complementary: their interaction term is high, and taken together they increase approval by 74 p.p. (marginal effect at the sample mean), against 64 p.p. for the combination of progressivity and self-interest, and 69 p.p. for self-interest and effectiveness. The combined effect on approval of the three motives with their strict definition reaches 97 p.p. Thus, in a scenario where everyone would believe in the effectiveness and progressivity of the policy, and the 70% of households who win would know it, our estimation indicates that the approval rate would be as high as 90%. These results suggest that the carbon tax aversion that appears at first sight is exclusively linked to biases in beliefs, and that if these biases were corrected for, carbon pricing could become close to consensual.

5.4.2 Willingness to pay

For respondents who believe in effectiveness of Tax & dividend, we are able to infer their willingness to pay (WTP) for climate mitigation by studying the acceptance rate in function of subjective gain. We adopt a common practice in the literature and define the WTP as the monetary loss that the *median* agent is willing to incur (Hanemann, 1984). Figure 4 indicates that this WTP is about 60€/year per c.u., as this corresponds to the subjective loss below which a majority accepts the policy. This WTP is computed only among people who believe that the tax is not ineffective, as it would make little sense to assume that some people are willing to pay for an instrument that does not achieve its expected goal. Indeed, Figure 4 shows that the “WTP” of the whole sample is zero, meaning that the median person accepts the policy only when they personally gain from it. Our method has several advantages. First, it can be interpreted as a willingness to accept as much as a willingness to pay, because our instrument is not framed as a good to buy nor as a damage to be compensated for, and net gains do not distinguish cost increases from payments received. Second, our method is more akin to revealed preferences — and hence probably less biased (Murphy et al., 2005) —

than previous ones, because most studies ask directly respondents to select their preferred
 720 option for climate mitigation, be it in a in a contingent valuation method (Berrens et al.,
 2004; Cameron, 2005; Kotchen et al., 2013) or in a discrete choice experiment (Longo et al.,
 2008; Alberini et al., 2018). Still, our estimation has two notable limitations relative to the
 literature: it relies on a non-representative sub-sample, and subjective gains are endogenous
 with acceptance. To compare our estimation with those of the literature, expressed per
 725 household, we have to multiply our WTP by the average number of consumption units by
 households: 1.6. The WTP per household we get, 96€, lies in the typical range of the
 literature (Jenkins, 2014; Streimikiene et al., 2019), suggesting that the protests against
 carbon taxation encountered in France do not reflect specific preferences for environmental
 policies.

730 [Figure 4 about here.]

6 Conclusion

In this paper, we investigate the relation between beliefs and acceptance of a carbon tax and
 dividend policy. Our analysis is based on a new survey and consumer survey data, enabling
 to compare subjective beliefs with objective impacts on French households. We find that 70%
 735 disapprove the proposed policy, which can be explained by biased beliefs about its properties.
 89% of our survey respondents overestimate the negative impact on their purchasing power,
 and most of them do not perceive it as environmentally effective nor progressive. Both their
 beliefs and revisions after facing new information appear too pessimistic. Biases in revisions
 are stronger for people opposed to the tax, indicating that beliefs about tax impacts are
 740 partly shaped by motivated reasoning. At the same time, we find that acceptance is causally
 determined by beliefs. In particular, when believing they would not lose or that the policy
 is effective, people are about 40 p.p. more likely to accept it. The effect of believing in
 progressivity is also large, at 27 p.p. Given the complementarity between motives, our results
 suggest that a majority of people can accept Tax & dividend on purely altruistic ground,

745 provided they believe in the fairness and efficacy of the reform. Adding to this the effect of self-interest for the 70% of households expected to win, we also find that if all biased beliefs could be corrected, the approval rate could reach 90%.

However, providing authentic arguments in favor of the scheme never convince more than 12% of people. We can relate this conservatism to a strong distrust of the government, 750 documented e.g. in [Alesina et al. \(2018\)](#). This result opens three main challenges. First, as it is unlikely that this trust issue can be resolved in the short run, it seems necessary to find climate policies that would be accepted by a majority. We address this question in a companion paper, in which we assess both knowledge and beliefs about climate change, and preferred policies of French people. Second, as trust in government needs to be restored in the 755 longer run, it is crucial to understand what causes the distrust and how it can be overcome. Third, it is important to assess to what extent our results are driven by the French context and influenced by the Yellow Vests movement. Although rejection of the tax may be lower in a different country, biases in perceptions are probably common everywhere. Thus, a lesson must be learned for policy design and implementation, to avoid a new carbon tax debacle à 760 *la Française*.

B Estimation for feedback

B.1 Formulas to compute monetary effects of carbon tax policy

In order to compute the monetary impact of a carbon tax increase, we decompose current energy expenditures $E(\tau)$ as a product of current price $P(\tau)$ and current quantities consumed $Q(\tau)$, each being a function of the excise tax τ within which the carbon tax is comprised:¹⁶

$$E(\tau) = P(\tau) Q(\tau)$$

All variations in expenditures can then be expressed as:

$$\frac{dE}{E}(\tau) = \frac{dP}{P}(\tau) + \frac{dQ}{Q}(\tau)$$

from which we can write the effect of a price change on quantities consumed:

$$Q(\tau') = Q(\tau) \left(1 + e \frac{dP}{P}(\tau) \right)$$

where $e = \frac{dQ}{dP} \cdot \frac{P}{Q}$ is the price elasticity of the energetic good considered, that is here assumed constant. For all energies, the final price can itself be decomposed as:

$$P(\tau) = (p + i\tau)(1 + t)$$

where t is the value added tax (VAT) rate that applies after excise taxes, i the incidence of excise taxes on consumers assumed constant, and $p + (i - 1)\tau$ the producer price as a

¹⁶The French carbon tax “Contribution Climat Energie” is a component of existing taxes on energetic products: TICPE for transport and domestic fuels, TICGN for natural gas.

770 function of τ and for a given value of t .¹⁷ When the carbon price changes so that the excise taxes varies from τ to some level τ' , we therefore have:

$$\frac{dP(\tau)}{P} = \frac{P(\tau') - P(\tau)}{P(\tau)} = \frac{(p + i\tau')(1 + t) - (p + i\tau)(1 + t)}{(p + i\tau)(1 + t)} = \frac{i(\tau' - \tau)}{p + i\tau}$$

Thus, following a carbon price increase, one can express the associated increase in expenditures for each energy as:

$$E(\tau') - E(\tau) = E(\tau)(1 + e) \frac{dP}{P} = E(\tau)(1 + e) \frac{i(\tau' - \tau)}{p + i\tau}$$

We can replicate similar calculations to obtain the expected variations in tax revenue T . Starting from its expression — which is the sum of excise taxes and the VAT over this tax — we have:

$$T(\tau) = Q(\tau)((1 + t)\tau + t(p + (i - 1)\tau))$$

from which we obtain:

$$T(\tau') - T(\tau) = Q(\tau) \left(1 + e \frac{i(\tau' - \tau)}{p + i\tau} \right) [t(p + (i - 1)\tau') + (1 + t)\tau'] - Q(\tau) [t(p + (i - 1)\tau) + (1 + t)\tau]$$

Following the literature, we assume price elasticities of -0.4 for transport fuels and -0.2 for housing energies. For the tax incidence on consumers, we assume a value of 0.8 . These values were used to compute aggregate variations in tax revenue and determine the level of lump sum transfer per adult that a budget neutral policy would finance. When asked to estimate the impact of the policy on their own purchasing power, respondents simply had to make an estimation over:

$$E(\tau') - E(\tau) = E(\tau)(1 + e) \frac{dP}{P}$$

where for simplicity dP was given for transport fuels, and $\frac{dP}{P}$ for housing energies. Thus, they were not required to make any specific assumption about existing taxes or tax incidence, but simply to estimate their consumption and price elasticity.

¹⁷Hence p is the producer price for a given value of t , when $\tau = 0$.

775 B.2 Predicting gains and losses

We regress the increase in housing energy expenditures on households' characteristic using EL 2013 survey. Table 11 presents several specifications for such regression, and its last row shows the out-of-sample error rate, computed with BdF data. All specifications yield a similar error rate of 15-17%. Fearing that respondents could make mistakes when filling
780 the accommodation size in the entry field, we used the first specification in our survey, as it does not rely as heavily as the others on the accommodation size. In order to balance the error rate for losing households that are mistakenly estimated winners, and winners who are mistakenly estimated losers, we add a constant of 16.1 in our estimation of yearly net gain, which is thus the sum of 16.1 plus 110 times one or two (depending on the number of
785 adults) minus increases in transport and housing energy expenditures. We selected OLS as our prediction method for the estimation of net gain because it compared well with respect to alternative methods. We also classified winners and losers using a decision tree, and obtained an very close error rate: 17.4% (see Figure 5). Finally, statistical matching provided an error rate of 17.7%.

E Control variables

Socio-demographics: *respondent's income, household's income, sexe, age* (5 categories), *employment status* (9 categories), *socio-professional category* (8 categories), *region of France*

815 (10 categories), *size of town* (5 categories), *diploma* 4 categories, *household size*, *number of people above 14*, *number of adults*, *number of c.u.*, *income per c.u.*, *smokes*, *avored media for news* (5 categories).

Politics: *extreme left*, *left*, *center*, *right*, *extreme right*, *interest in politics* (3 categories), *conservative*, *liberal*, *humanist*, *patriot*, *ecologist*, *apolitical*.

820 **Political leaning:** *extreme left*, *left*, *center*, *right*, *extreme right*, *indeterminate*.

Energy: *heating mode* (collective vs. indivual), *heating energy* (7 categories), *annual distance travelled*, *fuel economy*, *diesel* (binary), *gasoline* (binary), *number of vehicles*.

Incomes: *income of respondent*, *income of the second adult*, *income of respondent squared*, *income of the second adult squared*, *dummy for absence of second adult*.

825 **Estimated gains:** *simulated net gain*, *squared simulated gain*.

F Questionnaire

Priming

1. [No priming] Welcome to this survey.

It was conceived by two researchers in social science. It lasts about 15-20 minutes.

830 2. [Info PM] Welcome to this survey.

It was conceived by two researchers in social science. It lasts about 15-20 minutes.

Before starting, please read carefully the information below on particulate matter pollution:

- 835
- particulate matter are responsible for 48,000 deaths in France each year;
 - particulate matter reduce the life expectancy of French people by 9 months;

- reducing fuel consumption would reduce the health problems associated with particulate matter.

840 Source: [France Public Health Report \(2016\)](#)

3. [Info CC] Welcome to this survey.

It was conceived by two researchers in social science. It lasts about 15-20 minutes.

Please read carefully the information below on climate change.

845

- Climate change is already responsible for 150,000 deaths annually.
- If greenhouse gas emissions continue on their current trend, the average global warming will be +5°C in 2100 and +8°C in 2250.
- A rapid transition to renewable energies is technically possible and would contain global warming at +2°C.

850

According to scientists, in the absence of ambitious measures:

- a large proportion of species face an increased risk of extinction;
- natural disasters will intensify (hurricanes, heat waves, droughts, floods, forest fires, etc.);
- by 2100, 270 million more people would be flooded each year due to sea-level rise;
- violent conflicts and migration flows can be expected to increase.

855

Socio-demographics

860 4. What is your postal code?

5. What is your gender (in the sense of civil status)?

Female; Male

6. What is your age group?

18 to 24 years old; 25 to 34 years old; 35 to 49 years old; 50 to 64 years old; 65 years old

865 *or more*

7. What is your employment status?

Permanent; Temporary contract; Unemployed; Student; Retired; Other active; Inactive

8. What is your socio-professional category? (Remember that the unemployed are active workers).

870 *Farmer; Craftsperson, merchant; Independent; Executive; Intermediate occupation; Employee; Worker; Retired; Other Inactive*

9. What is your highest degree?

No diploma; Brevet des collèges; CAP or BEP [secondary]; Baccalaureate; Bac +2 (BTS, DUT, DEUG, schools of health and social training...); Bac +3 (licence...) [bachelor]; Bac
875 *+5 or more (master, engineering or business school, doctorate, medicine, master, DEA, DESS...)*

10. How many people live in your household? Household includes: you, your family members who live with you, and your dependents.

11. What is your net **monthly** income (in euros)? **All income** (before withholding tax) is
880 included here: salaries, pensions, allowances, APL [housing allowance], land income, etc.

12. What is the net **monthly** income (in euros) **of your household**? **All income** (before withholding tax) is included here: salaries, pensions, allowances, APL [housing allowance], land income, etc.

13. In your household how many people are 14 years old or older (including yourself)?

885 14. In your household, how many people are over the age of majority (including yourself)?

Energy characteristics

15. What is the surface area of your home? (in m²)

16. What is the heating system in your home?

Individual heating; Collective heating; PNR (Don't know, don't say)

890 17. What is the main heating energy source in your home?

Electricity Town gas; Butane, propane, tank gas; Heating oil; Wood, solar, geothermal, aerothermal (heat pump); Other; PNR (Don't know, don't say)

18. How many motor vehicles does your household have?

None; One; Two or more

895 19. [Without a vehicle] How many kilometers have you driven in the last 12 months?

20. [One vehicle] What type of fuel do you use for this vehicle?

Electric or hybrid; Diesel; Gasoline; Other

21. [One vehicle] What is the average fuel economy of your vehicle? (in Liters per 100 km)

22. [One vehicle] How many kilometers have you driven with your vehicle in the last 12

900 months?

23. [At least two vehicles] What type of fuel do you use for your main vehicle?

Electric or hybrid; Diesel; Gasoline; Other

24. [At least two vehicles] What type of fuel do you use for your second vehicle?

Electric or hybrid; Diesel; Gasoline; Other

905 25. [At least two vehicles] What is the average fuel economy of all your vehicles? (in Liters per 100 km)

26. [At least two vehicles] How many kilometers have you driven with all your vehicles in the last 12 months?

Partial reforms [transport / housing]

- 910 27. Do you think that an increase in VAT would result in a loss of more purchasing power for your household than for the average French household?

Yes, much more; Yes, a little more; As much as the average; No, a little less; No, a lot less; PNR (Don't know, don't say)

28. Do you think that an increase in [fuel taxes / taxes on gas and heating oil] would cause
915 your household to lose more purchasing power than an average French household?

Yes, much more; Yes, a little more; As much as the average; No, a little less; No, a lot less; PNR (Don't know, don't say)

29. The government is studying a fuel tax increase, whose revenues would be redistributed to all households, regardless of their income. This would imply:

- 920 • [an increase in the price of gasoline by 11 cents per liter and diesel by 13 cents per liter / a 13% increase in the price of gas, and a 15% increase in the price of heating oil];
- an annual payment of [60 / 50]€ to each adult, or [120 / 100]€ per year for a couple.

- In terms of purchasing power, would your household be a winner or a loser
925 with such a measure?**

Winner; Unaffected; Loser

30. [*Winner* selected] **According to you, your household's purchasing power would increase:**

930 *From 0 to [10·uc]€ per year; From [10·uc] to [20·uc]€ per year; From [20·uc] to [30·uc] € per year; From [30·uc] to [40·uc]€ per year; More than [40·uc]€ per year*

31. [*Loser* selected] **According to you, the purchasing power of your household would decrease:**

From 0 to [15·uc]/€ per year; From [15·uc] to [40·uc]/€ per year; From [40·uc] to [70·uc] € per year; From [70·uc] to [110·uc]/€ per year; From [110·uc] to [160·uc]/€ per year; From more than [160·uc]/€ per year

32. If fuel prices increased by 50 cents per liter, by how much would **your household** reduce its fuel consumption?

0% - [I already consume almost none / I am already not consuming]; 0% - [I am constrained on all my trips / I will not reduce it]; From 0% to 10%; From 10% to 20%; From 20% to 30%; More than 30% - [I would change my travel habits significantly / I would change my consumption significantly]

33. In your opinion, if [fuel prices increased by 50 cents per liter / gas and heating oil prices increased by 30%], by how much would **French people** reduce their consumption on average?

From 0% to 3%; From 3% to 10%; From 3% to 10%; From 10% to 20%; From 20% to 30%; More than 30%

Tax & dividend: initial

34. The government is studying an increase in the carbon tax, whose revenues would be redistributed to all households, regardless of their income. This would imply:

- an increase in the price of gasoline by 11 cents per liter and diesel by 13 cents per liter;
- an increase of 13% in the price of gas, and 15% in the price of heating oil;
- an annual payment of 110€ to each adult, or 220€ per year for a couple.

In terms of purchasing power, would your household win or loser with such a measure?

Win; Be unaffected; Lose

35. [*Winner* selected] **According to you, your household's purchasing power would increase:**

From 0 to [20·uc]€ per year; From [20·uc] to [40·uc]€ per year; From [40·uc] to [60·uc] € per year; From [60·uc] to [80·uc]€ per year; From more than [80·uc]€ per year

36. [*Loser* selected] **According to you, the purchasing power of your household would decrease:**

From 0 to [30·uc]€ per year; From [30·uc] to [70·uc]€ per year; From [70·uc] to [120·uc] € per year; From [120·uc] to [190·uc]€ per year; From [190·uc] to [280·uc]€ per year; From more than [280·uc]€ per year

37. [[empty] / Scientists agree that a carbon tax would be effective in reducing pollution.]
Do you think that such a measure would reduce pollution and fight climate change?
Yes; No; PNR (Don't know, don't say)

38. In your opinion, which categories would lose [[blank] / purchasing power] with such a measure? (Several answers possible)

No one; The poorest; The middle classes; The richest; All French people; Rural or peri-urban people; Some French people, but not a particular income category; PNR (Don't know, don't say)

39. In your opinion, what categories would gain purchasing power with such a measure? (Several answers possible)

No one; The poorest; The middle classes; The richest; All French people; Urban dwellers; Some French people, but not a particular income category; PNR (Don't know, don't say)

Tax & dividend: after knowledge

40. [Feedback] We always consider the same measure. As a reminder, it would imply:

- an increase in the price of petrol by 11 cents per liter and diesel by 13 cents per liter;
- an increase of 13% in the price of gas, and 15% in the price of heating oil;

- an annual payment of 110€ to each adult, or 220€ per year for a couple.

In five out of six cases, a household with the same characteristics as yours would **[win / lose]**. (The characteristics taken into account are: heating with [source] for a dwelling of
 985 [size] m²; [distance] km covered with an average consumption of [fuel economy] liters per 100 km).

Based on this estimate, do you now think that your household would be:

Winner; Unaffected; Loser

990 41. [Info on progressivity] On average, this measure would increase the purchasing power of poorest households, and decrease that of the richest, who consume more energy.

In view of this new information, do you think this measure would benefit the poorest?

Yes; No; PNR (Don't know, don't say)

995 42. [No info on progressivity] Do you think this measure would benefit the poorest?

Yes; No; PNR (Don't know, don't say)

43. In view of the above estimate, would you approve of such a measure?

Yes; No; PNR (Don't know, don't say)

44. Why do you think this measure is beneficial? (Maximum three responses)

1000 *Contributes to the fight climate change; Reduces the harmful effects of pollution on health; Reduces traffic congestion; Increases my purchasing power; Increases the purchasing power of the poorest; Fosters France's independence from fossil energy imports; Prepares the economy for tomorrow's challenges; For none of these reasons; Other (specify):*

45. Why do you think this measure is unwanted? (Maximum three answers)

1005 *Is ineffective in reducing pollution; Alternatives are insufficient or too expensive; Penalizes rural areas; Decreases my purchasing power; Decreases the purchasing power of some*

*modest households; Harms the economy and employment; Is a pretext for raising taxes;
For none of these reasons; Other (specify):*

Tax & targeted dividend

1010 46. The government is studying an increase in the carbon tax, whose revenues would be redistributed to the [20 / 30 / 40 / 50]% of the poorest French people only. This would imply:

- an increase in the price of gasoline by 11 cents per liter and diesel by 13 cents per liter;
- an increase of 13% in the price of gas, and 15% in the price of heating oil;
- 1015 • an annual payment of [550 / 360 / 270 / 220]€ for each adult earning less than [780 / 1140 / 1430 / 1670]€ per month (welfare benefits included, before withholding tax);
- no compensation for the others.

We estimate that in your household, [number of recipients] persons would receive this payment.

1020

In terms of purchasing power, would your household win or lose with such a measure?

Win; Be unaffected; Lose

47. Would you approve such a measure?

Yes; No; PNR (Don't know, don't say)

1025 **Other questions** The survey is completed by other attitudinal questions, treated in our companion paper ([Douenne & Fabre, 2019](#)). Hereafter, we only describe questions that are used in the present paper.

48. Please select “A little” (test to check that you are attentive).

Not at all; A little; A lot; Completely; PNR (Don't know, don't say)

1030 49. Do you smoke regularly?

Yes; No

50. How much are you interested in politics?

Almost not; A little; A lot

51. How would you define yourself? (Several answers possible)

1035 *Extreme left; Left; Center; Right; Extreme right; Liberal; Conservative; Liberal; Humanist;
Patriot; Apolitical; Ecologist*

52. How do you keep yourself informed of current events? Mainly through...

Television; Press (written or online); Social networks; Radio; Other

53. What do you think of the Yellow Vests? (Several answers possible)

1040 *I am part of them; I support them; I understand them; I oppose them; PNR (Don't know,
don't say)*

54. The survey is nearing completion. You can now enter any comments, comments or suggestions in the field below.
